

AI-enabled legal technology support

Discussion follow-up · synthetic proof of concept · September 2026

The proposition

Use AI to prepare a better next action while deterministic controls and accountable people retain authority. Continue investing only when quality, safety, useful adoption and full-cost evidence justify it.

What the prototype demonstrates

- A repeatable support pattern: frame the need, use permitted evidence, prepare a proposal, apply controls and measure the outcome.
- Safe handling of normal and failure cases, including duplicate prevention, timeout recovery, restricted access and invalid reference data.
- Reusable prompts, skills and review automations with versioning, named approval, rollback, retirement and explicit stop conditions.
- Visible quality, model-use and cost evidence beside the operational result.

What it does not claim

The demonstration uses fictional people, matters, clients, tickets and outcomes. It is not ABL data, architecture or configuration, and it does not establish realised savings, professional-quality improvement, adoption or commercial return.

A proportionate pilot

1 · Baseline

Select one recurring support need and measure current handling, quality, rework and cost.

2 · Pilot

Use bounded approved data, named owners, human review, an evaluation set and clear stop conditions.

3 · Decide

Compare accepted quality, safety, adoption and full cost; keep, change, replace, retire or stop.

Suggested next conversation

Identify one service problem worth testing, the accountable owner, the evidence needed to judge it and the conditions that would stop the experiment. The private technical repository is available if a deeper engineering review is useful; it is supporting material, not the primary experience.
